

Funnel Conversion Analysis

Dataset Overview

- 600 candidates
- 100 requisitions
- 6 recruiters
- Timeline: January 2025 → June 2025

The analysis focused on identifying:

- conversion bottlenecks;
- recruiter performance patterns;
- sourcing channel efficiency;
- candidate progression signals;
- and operational opportunities to improve hiring outcomes.

Funnel Overview

The funnel suggests that the operation already generates meaningful pipeline volume, but loses efficiency in mid and late funnel stages.

Top of Funnel

Approximately:

~32% of candidates did not respond to the first outreach.

This indicates that a significant portion of sourcing effort does not convert into active pipeline generation.

Possible causes identified:

- low personalization;
- generic outreach messaging;
- limited use of multi-channel engagement;
- low-context first contact.

Mid Funnel

Candidates generally progressed through:

- sourcing;
- screening;
- interviews;
- technical assessment.

At this stage, the pipeline quality becomes significantly stronger.

The dataset suggests that:

- candidates reaching testing stages already represent meaningful operational investment;
- and conversion optimization becomes more valuable than increasing sourcing volume.

Late Funnel

The largest operational bottleneck appears after testing.

A significant number of candidates completed assessments but did not convert to hiring, including candidates with strong evaluation scores.

Among candidates lost after testing:

- all completed both technical and behavioral assessments;
- 42.8% had at least one score ≥ 80 ;
- 9 candidates had both technical and behavioral scores ≥ 80 .

This suggests that part of the loss happens after identifying already-qualified talent.

Relevant Insights

1. Balanced candidate quality predicts hiring better than isolated excellence

Candidates with:

- technical ≥ 80 ;
- behavioral ≥ 80 ;

showed approximately:

~2x higher hiring conversion than the dataset average.

Meanwhile:

- candidates with technical ≤ 70 AND behavioral ≤ 70 had:

0% hiring conversion.

This suggests that hiring outcomes correlate more strongly with balanced candidate quality than with isolated strength in a single dimension.

2. Technical score is the strongest isolated hiring signal

Technical assessment score showed the strongest individual correlation with hiring progression among all available scoring metrics.

However, the combination of:

- technical;
- behavioral;
- and recruiter interaction quality

appears more predictive than any single score alone.

3. Recruiter specialization patterns emerged clearly

Some recruiters consistently performed better within specific role families.

Examples:

- Bruno showed stronger late-stage conversion in People and Talent Acquisition roles;
- Ana showed stronger sourcing and conversion efficiency in Data and technical positions.

The data suggests that recruiter specialization may improve:

- sourcing calibration;
- hiring manager alignment;
- and conversion consistency.

4. Github was the strongest sourcing channel

Github produced the highest hiring conversion rate in the dataset, particularly for technical profiles.

This suggests that:

- targeted sourcing strategies outperform generalized outbound approaches;
- especially for technical and analytical roles.

Referral sourcing, on the other hand, showed relatively weak conversion during the analyzed period.

5. ATS hygiene inconsistencies may affect visibility

Some candidates completed testing stages while appearing under inconsistent final pipeline stages in the ATS.

This may impact:

- funnel visibility;
- reporting reliability;
- and stage conversion analysis.

Practical Recommendations for Recruiters

1. Increase specialization within the recruiting team

Instead of distributing requisitions uniformly, organize recruiters around:

- role families;
- candidate types;
- or sourcing strengths.

Suggested specialization examples:

- Bruno → People / TA / high-touch hiring
- Ana → Data / technical sourcing / Github outreach

This may improve:

- recruiter calibration;
- sourcing precision;
- and candidate conversion.

2. Improve top-of-funnel outreach quality

Given the ~32% non-response rate, the operation may benefit from:

- more personalized outreach;
- clearer value propositions;
- multi-touch engagement;
- higher-touch communication for strategic hires.

Potential experiments:

- WhatsApp/phone follow-up;
- OSINT-assisted personalization;
- segmented messaging by role type.

3. Prioritize high-potential candidates after testing

The strongest ROI opportunity appears in improving conversion among already-qualified candidates.

Candidates with:

- high technical scores;
- high behavioral scores;
- advanced funnel progression;

should receive:

- faster feedback;
- structured follow-up;
- active candidate nurturing;
- and higher recruiter persistence.

4. Accelerate decisions on historically low-conversion profiles

Candidates with:

- technical ≤ 70 ;
- behavioral ≤ 70 ;

showed 0% hiring conversion

This creates an opportunity to:

- reduce operational effort on low-probability profiles;

- improve recruiter focus allocation;
- and shorten pipeline cycles.

5. Standardize ATS stage management

Improving pipeline hygiene may increase:

- reporting reliability;
- recruiter visibility;
- and operational forecasting accuracy.

Applied Use of AI in the Workflow

One proposed AI application is the creation of a: “Hireability Score”

Possible Inputs

The model could combine:

- technical assessment score;
- behavioral assessment score;

Expected Outputs

The AI layer could generate:

- hiring likelihood estimation;
- recruiter prioritization queues;
- late-stage dropout risk alerts;
- candidate persistence recommendations;
- and hiring forecasts.

Operational Impact

This approach could help:

- reduce effort spent on low-conversion profiles;
- improve persistence with high-potential candidates;
- increase recruiter efficiency;
- improve forecasting;
- and optimize funnel conversion without necessarily increasing sourcing volume

Final Conclusion

Across six months of recruiting activity, the dataset suggests that the operation's largest opportunity is not pipeline generation, but improving conversion efficiency among already-qualified candidates.

The strongest improvements likely come from:

- recruiter specialization;
- better post-test candidate management;
- stronger outreach personalization;
- and AI-assisted prioritization of high-potential profiles.
